A.1:

The "poly" command is used to turn a matrix that contains the roots of an equation back into the original polynomial equation.

Matlab

```matlab
% Set component values:
R = [1e4, 1e4, 1e4]; C = [1e-6, 1e-6];
% Determine the coefficients for characteristic equation:
A1 = [1, (1/R(1)+1/R(2)+1/R(3))/C(2), 1/(R(1)*R(2)*C(1)*C(2))];
% Determine characteristic roots:
lambda = roots(A1);

%The poly command takes in the matrix of roots and  returns the original
%polynomial equation.
poly(lambda)
```

A.2:

Matlab:

```matlab
% Set component values:
R = [1e4, 1e4, 1e4]; C = [1e-6, 1e-6];
% Determine the coefficients for characteristic equation:
A1 = [1, (1/R(1)+1/R(2)+1/R(3))/C(2), 1/(R(1)*R(2)*C(1)*C(2))];
% Determine characteristic roots:
lambda = roots(A1);

%The poly command takes in the matrix of roots and  returns the original
%polynomial equation.
poly(lambda);

t = [0:0.0005:0.1];
u = @(t) 1.0* (t>=0);
```

```matlab
h = @(t) (C(1).* exp(lambda(1).* t) + C(2).* exp(lambda(2).*t)).*(u(t));

plot(t,h(t))
```

A.3:
Matlab:

```matlab
function[lambda] = CH2MP2(R,C)

%Determine the coefficients for characteristics equation.
A = [1, (1/R(1)+1/R(2)+1/R(3))/C(2), 1/(R(1)*R(2)*C(1)*C(2))];

% Determine characteristic roots:
lambda = roots(A)
```

I observed that all the convolutions has parts of them that were similar to the sin(t) function. I also observed that the duration of the signal resulting from the convolution of two signals is that the duration of the convolution is equal to the sum of the duration of the functions. There is a relationship between S2, S3, and S4. S2 and S3 have about the same convolution. S4 has a similar convolution to S2 and S3.

Overall convolution for all regions performed by hand is similar to those performed using Matlab, same results were obtained.

D2: The observations that can be made about the width/duration of the signal resulting from the convolution of two signals is that the duration of the convolution is equal to the sum of the duration of the functions.
